## Acknowledgements

The authors would like to acknowledge the contribution of Professor Annie Anderson, Dr Julie Armstrong and Dr Andrea Sherriff and Food Standards Scotland staff, in particular Anne Milne, Gillian Purdon and Heather Peace, and thank them for their support and guidance throughout the project.

The authors would also like to thank the staff of Defra, York and London for their invaluable help with interpreting the data and formulating the calculations required for analysis of the Living Costs and Food Survey (LCFS) data, and in providing data ahead of it becoming available on the UK Data Archive, in particular Jim Holding, Clare Burgon, David Lee and Andrew Scaife. In addition, we thank the staff at the Office for National Statistics (ONS), Newport, Wales for their assistance in providing data on sampling and income variables, for mapping Scottish Index of Multiple Deprivation (SIMD) data to the LCFS households and in providing data ahead of it becoming available on the UK Data Archive.

This work was carried out using LCFS data from the UK Data Archive, University of Essex (http://www.dataarchive.ac.uk/), which was provided ahead of it becoming publically available by the UK Data Archive by Defra and ONS. Additional variables on sampling and income were provided by ONS, and SIMD data were obtained from Scottish Neighbourhood Statistics.

## Executive Summary

## Introduction

In 2013, Revised Dietary Goals for Scotland were published, updating the 1996 Scottish Dietary Targets. These goals encompassed recommendations for intakes of both foods and nutrients, similar to those in the original targets regarding fruit and vegetables, oily fish, total fat, saturated fat, sugar (NMES), and salt. However, goals were added with regard to red meat, energy, energy density, trans fatty acids, and fibre as non-starch polysaccharides (NSP).

Progress towards the goals is monitored using a combination of surveys, but principally via secondary analysis of the Living Costs and Food Survey (LCFS) data from 2001 to date, following the endorsement of the 2004 Working Group Report on Monitoring Scottish Dietary Targets which concluded that it was the most appropriate method for Scotland. Other Scottish surveys that collect data on dietary intake, such as the Scottish Health Survey, do not provide data suitable for monitoring the goals.

The results provided in this report support work by Food Standards Scotland and the Scottish Government to facilitate improvements to the diet in Scotland to help reduce the burden of obesity and diet-related disease.

## Objective

The purpose of this work was to obtain robust estimates of food consumption and nutrient intakes for 2013 to 2015 in Scotland in order to continue to monitor progress toward the 2013 Scottish Dietary Goals. More specifically, the aims were to calculate the results for the years 2013 to 2015, and to assess differences in food consumption and nutrient intakes over time and by Scottish Index of Multiple Deprivation (SIMD) quintile. Furthermore, the main contributors to intakes of energy, fat, saturated fat, NMES and NSP were explored.

## Methods

LCFS data for each year, in its raw form, was obtained from Defra and the UK Office for National Statistics (ONS) (prior to it being made publically available on the UK Data Archive, University of Essex). Data on sampling methodology were obtained from ONS who also mapped SIMD quintiles to the data. Food consumption and nutrient intake in Scotland calculated in the previous reports was updated by the addition of the years 2013 to 2015. Analysis was also carried out by SIMD quintile for the period of 2013 to 2015. Adjustments were made to allocate the correct proportion of each food to the appropriate food group and for waste. In addition, the contribution that food groupings made to intakes of energy, fat, saturated fat, NMES and NSP were also explored. Data were analysed weighting to the Scottish population and taking account of sampling methods. Results are presented as population means (i.e. including consumers and non-consumers) for household and eating out foods combined.

## Key Findings for 2001-2003 to 2013-2015: Scottish Dietary Goals

- There was little progress towards meeting the 2013 Scottish Dietary Goals over the 15 year period. This lack of progress was apparent even amongst households in the least deprived areas.
- Fruit and vegetable consumption did not change between 2001-2003 and 2013-2015.
- Oil rich fish consumption did not change.
- Total red and processed meat consumption reduced over the 15 year period, and average consumption met the goal.
- Energy density of the diet has increased.
- Total fat intake did not change but saturated fat intake (as a percentage of food energy) reduced, however mean intakes of both total and saturated fat remain higher than the goals.
- NMES intake (as a percentage of food energy) reduced, however mean intake remains considerably higher than the goal.
- In 2013-2015, households in the most deprived areas consumed significantly less fruit and vegetables, oil rich fish and fibre than households in the least deprived areas, but there was no difference in the consumption of red and processed meat by deprivation category. However, intakes of fruit and vegetables, oil rich fish and fibre remain considerably lower than the goals for all SIMD quintiles.
- There was no difference in the energy density of the diet or in total fat, saturated fat or NMES intakes by level of deprivation.
- Where a difference existed between households in the least and most deprived areas, there was no evidence to suggest that the gap in intake had changed compared to previous years.

Mean food and nutrient intakes in relation to the Scottish Dietary Goals from 2001 to 2015

| Food / Nutrient | Scottish Dietary Goal | $\begin{aligned} & \text { 2001- } \\ & 2003 \end{aligned}$ | $\begin{aligned} & 2013- \\ & 2015 \end{aligned}$ | $\begin{gathered} \hline \text { Change between } \\ 2001-2003 \text { and } \\ 2013-2015^{1} \\ \hline \end{gathered}$ | Highest consumption by SIMD in $2013-2015^{1,2}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Energy density (kcal/100g) | Average energy density of the diet to be lowered to $125 \mathrm{kcal} / 100 \mathrm{~g}$ | 171 | 175 | $\uparrow$ | No Difference |
| Fruit and Vegetables (g/day) | At least 5 portions per person per day (> $400 \mathrm{~g} / \mathrm{day}$ ) | 256 | 258 | No Change | Least Deprived |
| Oil rich fish (g/week) | Increase to one portion per person (140g) per week | 29 | 29 | No Change | Least Deprived |
| Red Meat (g/day) | Average intake of red and processed meat to be pegged at around 70 g per person per day | 65 | 56 | $\downarrow$ | No Difference |
| Fat <br> (\% food energy) | $\leq 35 \%$ food energy | 38.8 | 39.3 | No Change | No Difference |
| Saturated Fat (\% food energy) | $\leq 11 \%$ of food energy | 15.6 | 15.3 | $\downarrow$ | No Difference |
| Sugar <br> (\% food energy) | NMES $^{3}$ to reduce to less than $11 \%$ of food energy in children and adults | 15.7 | 14.3 | $\downarrow$ | No Difference |
| Fibre (g/day) | Increase in average consumption of fibre ${ }^{4}$ to 18g/day | 12 | 12 | No Change | Least Deprived |

[^0]
## Key Findings for 2001-2003 to 2013-2015: Additional Foods and Drinks Indicative of Diet Quality

- Total bread consumption decreased, however brown/wholemeal bread, high fibre and total breakfast cerea consumption remained fairly constant.
- Consumption of discretionary foods such as cakes, sweet biscuits, and confectionery remained fairly constant.
- Sugar containing soft drinks consumption decreased from $245 \mathrm{~g} /$ day to $156 \mathrm{~g} /$ day, and consumption of sugar free soft drinks increased, but not at the same rate.
- Bacon and ham consumption remained fairly constant, but consumption of other processed red meat products including savoury pies decreased significantly.
- Total spread consumption decreased, however this was due to a reduction in low fat spread consumption as butter and margarine consumption increased.
- Total milk consumption decreased.
- White fish consumption decreased by almost 20 g per week.
- Fresh potato consumption decreased by 20 g per day.
- Processed potato and savoury snack consumption did not change.
- Nut consumption increased.
- In 2013-2015, households in the most deprived areas consumed significantly less brown/wholemeal bread, breakfast cereal, skimmed milk, cheese, cream, white fish and nuts than households in the least deprived areas, and more sugar containing soft drinks, processed red meat products (with the exception of bacon and ham) and whole milk.

## Key Findings: Contribution of Foods to Intakes of Energy, Fat, Saturated Fat, and NMES

- Discretionary foods that are high in sugar and fat, namely sweet biscuits; confectionery; crisps and savoury snacks; cakes, pastries and puddings; and sugar sweetened beverages are significant contributors to energy in the diet. Sweet biscuits, in particular are one of the top five contributors to energy, fat, saturated fat and NMES.
- These five food groupings contribute almost $20 \%$ of energy, fat and saturated fat intakes and more than $50 \%$ of NMES intake.
- Significant reductions were found between 2001-2003 and 2013-2015 in the percentage contribution of processed red meat, bread and rolls, and milk to energy intake; processed red meat and milk to fat and saturated fat intake, and sugar containing soft drinks and sugar to NMES intake due to consumption of these foods and drinks reducing.
- Between 2001-2003 and 2013-2015, sweet biscuits contributed less to saturated fat intake and more to NMES intake, both in terms of absolute weight and percentage contribution.
- The contributions of total processed red meat, sugar containing soft drinks, whole milk, and processed potatoes to intakes of energy, fat, saturated fat, NMES and/or NSP were greater in the most deprived, whereas the contributions of total fruit and vegetables; total breakfast cereal; other baked goods; cream; nuts; jam, marmalade, honey and sweet spreads; and unprocessed fish to these nutrients were greater in the least deprived.

Mean contribution of selected discretionary foods and drinks to energy, fat, saturated fat and NMES intake in 2013-2015 (intake (percentage) per person per day)

|  | Weight <br> $\mathbf{g}$ | Energy <br> $\mathbf{k c a l}(\%)$ | Fat <br> $\mathbf{g}(\%)$ | Saturated Fat <br> $\mathbf{g ~ ( \% ) ~}$ | NMES <br> $\mathbf{g ~ ( \% ) ~}$ |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Sweet Biscuits | 21.6 | $103(5.3)$ | $4.9(5.9)$ | $2.5(7.7)$ | $5.7(8.0)$ |
| Total Confectionery | 21.2 | $92.2(4.7)$ | $3.7(4.5)$ | $2.0(6.3)$ | $12.8(17.9)$ |
| Crisps and Savoury Snacks | 13.4 | $67.1(3.4)$ | $3.8(4.5)$ | $0.5(1.6)$ | $0.02(0.02)$ |
| Cakes, Pastries and Puddings | 16.5 | $59.7(3.1)$ | $2.8(3.3)$ | $1.2(3.7)$ | $4.4(6.2)$ |
| Sugar Containing Soft Drinks | 156 | $57.0(2.9)$ | Nil | Nil | $14.9(20.8)$ |
| Total |  | $379(19.4)$ | $15.2(18.2)$ | $6.2(19.3)$ | $37.8(52.9)$ |

## Conclusion

A robust standardised methodology, used to calculate food and nutrient intakes on a population basis over a fifteenyear period, has allowed comparisons to be made over time, enabling a clear assessment of any dietary change. As with previous monitoring of the Scottish diet, little change has been found since 2001. Clear differences between households in the least and most deprived areas continue to be apparent in food consumption for the period 2013 to 2015. This work continues to be an important part of Food Standards Scotland's dietary surveillance programme.

| > | greater than |
| < | less than |
| \% | percent / percentage |

| Confidence Interval (Cl) and <br> 95\% Confidence Interval ( $95 \% \mathrm{Cl}$ ) of the Mean | A range of values that, it is estimated includes a population statistic at a specific level of confidence. The $95 \%$ confidence interval $(95 \% \mathrm{Cl})$ of the mean refers to the range of values 2 standard errors above and 2 standard errors below the mean. There is only a $5 \%$ chance that this range excludes the true mean of the population. The $95 \%$ confidence interval ( Cl ) calculates the region around the mean where the true figure is likely to be. The narrower the confidence interval about the observed mean the more reliable it is. |
| :---: | :---: |
| Food Energy | The energy obtained from food and drink (excluding alcohol). |
| Mean | The mean intake is calculated by summing all intakes and dividing by the total number of people in the sample. Therefore it is moderated by the high and/or low consumers. When there are non-consumers in the sample (i.e. those with an intake $=0$ ) the population average must take these into account. The $95 \% \mathrm{Cl}$ calculates the region around the mean where the true figure is likely to be. The narrower the $95 \% \mathrm{Cl}$ of the observed mean the more reliable it is. |
| Median | The median is the middle value of a set of figures, i.e. for an odd number of cases the median is the middle score. For an even number of cases the median is the average of the two middle scores. For normally distributed data the mean equals the median. <br> The interquartile range represents $25 \%$ of values either side of the median. <br> Data on food consumption and nutrient intake in a population is not usually normally distributed, some intakes will be very high or very low e.g. vitamin C or oil rich fish. For this reason it is more meaningful to give median food consumption and nutrient intake and to show interquartile ranges. This allows the proportion of low (e.g. for fruit and vegetables) or high consumers (e.g. for NMES) to be placed relative to the goal. Due to the nature of the LCFS data it is not possible to produce reliable medians. |
| Non-Milk Extrinsic Sugars (NMES) | Sugars, excluding those in milk and milk products that are not incorporated into the cellular structure of foods, such as fruit and vegetables e.g. sugar released from fruit when it is blended or juiced, table sugar, honey and added sugar in cakes, biscuit, sweets, breakfast cereals and soft drinks. |
| Percentage Food Energy (\% Food Energy) | The percentage of food energy (the energy obtained from food and drink (excluding alcohol)) intake derived from a macronutrient i.e. fat, carbohydrate or protein. |
| Quintile | The portion of a frequency distribution containing one fifth of the total sample. For example the first quintile is the point with $1 / 5$ of the data below it and $4 / 5$ above it. |
| Scottish Index of Multiple Deprivation (SIMD) | The Scottish Index of Multiple Deprivation (SIMD) 2004, 2006, 2009 and 2012 identifies the most deprived areas across Scotland. It is based on indicators within seven individual domains of Current Income, Employment, Housing, Health, Education, Skills \& Training, Geographic Access to Services \& Telecommunications and Crime (which was added in 2006). SIMD is presented at data zone level, enabling small pockets of deprivation to be identified. The data zones are ranked from most deprived (1) to least deprived (6505) on the overall SIMD 2004 and on each of the individual domains. The 6505 data areas are ranked according to level of deprivation; these are then usually split into deciles with 1 being most deprived and 10 being most affluent. In this report the deciles have been combined to give quintiles. Thus Quintile 1 combines the most deprived deciles 1 and 2. SIMD 2004 was used for the analysis of data from 2001-2006, SIMD 2009 was used for the analysis of data from 2007-2009 and SIMD 2012 was used for the analysis of data from 2010-2015. |

| Sodium | Sodium chloride is the chemical name for salt. 100 millimoles of sodium is equivalent to the Scottish Dietary Goal of 6 g of salt based on SACN advice. |
| :---: | :---: |
| Significant | The term significant refers to statistical significance (at the 95\% level). It is not intended to imply substantive importance. |
| Takeaway Foods | Any food bought for consumption within the home is classed as household purchases. This includes for example, fish and chips; drive through brought home; home deliveries of: pizza, Chinese and Indian meals (Defra, 2009). |
| UK Data Archive | The UK Data Archive is a centre of expertise in data acquisition, preservation, dissemination and promotion and is curator of the largest collection of digital data in the social sciences and humanities in the UK. |
| Years | For the purposes of this report, for ease of understanding, dates have been presented in the text as single years: <br> 2001 = 2001/2002, which refers to April 2001 to March 2002 <br> 2002 = 2002/2003, which refers to April 2002 to March 2003 <br> 2003 = 2003/2004, which refers to April 2003 to March 2004 <br> 2004 = 2004/2005, which refers to April 2004 to March 2005 <br> 2005 = 2005/2006, which refers to April 2005 to March 2006 <br> 2006 onwards = refers to Jan to Dec of the year in question <br> From 2006 the EFS moved from a financial year to a calendar year basis. As a consequence of this the January to March 2006 data are duplicated in the 2005/2006 and the 2006 results. Removing the duplicated quarter from one of the years (2005/2006 or 2006) would have led to a smaller sample for the year in question which may have not been representative and may have been skewed due to seasonal purchases. |
| Periods | 2001-2003 or $1^{\text {st }}$ period $=2001 / 2002$ - 2003/2004, which refers to April 2001 to March 2004 <br> 2004-2006 or $2^{\text {nd }}$ period $=2004 / 2005-2006$, which refers to refers to April 2004 to December 2006 <br> 2007-2009 or 3rd period refers to January 2007 to December 2009 2010-2012 or $4^{\text {th }}$ period refers to January 2010 to December 2012 2013-2015 or $5^{\text {th }}$ period refers to January 2013 to December 2015 |

### 1.1 The Scottish Dietary Goals

In 1996, Scottish Dietary Targets (SDTs) were set as part of the Scottish Diet Action Plan (Scottish Office, 1996) in response to a report published by the Scottish Office in 1993 which highlighted the need for "radical change in Scotland...to achieve the health targets for 2000" (Scottish Office, 1993). These targets were based on the UK Dietary Reference Values (Department of Health, 1991) for selected nutrients (total fat, saturated fatty acids, salt, sugar as non-milk extrinsic sugars (NMES) and total complex carbohydrates) and also included key foods (fruit and vegetables, bread, breakfast cereals, white fish and oil rich fish). The baseline figures used in the setting of these targets were derived mainly from the National Food Surveys of 1989-1991 and were an indication of food and nutrient intake at that time. The SDTs were originally intended for achievement in 2005, but the timescale was extended to 2010 (Scottish Executive, 2003, Scottish Executive, 2004).

In 2013, Revised Dietary Goals for Scotland were published, updating the previous SDTs to "indicate the direction of travel, and assist policy development to reduce the burden of obesity and diet-related disease in Scotland" and to help to "facilitate improvements in the Scottish diet" (Scottish Government, 2013). These goals encompassed recommendations for intakes of both foods and nutrients, similar to those in the original SDTs regarding fruit and vegetables, oily fish, total fat, saturated fat, NMES, and salt. However, targets for consumption of bread, breakfast cereal and white fish were removed, and goals were added with regard to red meat, energy, energy density, trans fatty acids, and fibre as non-starch polysaccharides (NSP) (Table 1).

Table 1: Revised Dietary Goals for Scotland (Scottish Government, 2013)

| Calories | A reduction in calorie intake by 120 kcal/person/day* <br> Average energy density of the diet to be lowered to $125 \mathrm{kcal} / 100 \mathrm{~g}$ by reducing intake of <br> high fat and/or sugary products and by replacing with starchy carbohydrates (e.g. bread, <br> pasta, rice and potatoes), fruits and vegetables |
| :--- | :--- |
| Fruit \& Vegetables | Average intake of a variety of fruit and vegetables to reach at least 5 portions per person <br> per day (> 400g per day) |
| Oily Fish | Oil rich fish consumption to increase to one portion per person (140g) per week |
| Red Meat | Average intake of red and processed meat to be pegged at around 70g per person per day <br> Average intake of the very highest consumers of red and processed meat (90g per person <br> per day) not to increase* |
| Fats | Average intake of total fat to reduce to no more than $35 \%$ food energy <br> Average intake in saturated fat to reduce to no more than $11 \%$ food energy <br> Average intake of trans fatty acids to remain below $1 \%$ food energy* |
| Sugar | Average intake of NMES ${ }^{1}$ to reduce to less than 11\% of food energy in children and adults |
| Salt | Average intake of salt to reduce to 6g per day* |

*Not monitored using data from the LCFS; ${ }^{1}$ NMES (Non-milk Extrinsic Sugars) are also known as added or free sugars and are found in sweets, biscuits, soft drinks, added to breakfast cereals, table sugar, honey and fruit juice. They are not in milk or integrally present in the cells of food such as fruit and vegetables; ${ }^{2}$ Non-starch polysaccharide (NSP) as measured by Englyst method.

### 1.2 Monitoring Progress towards the Scottish Dietary Goals

Progress towards the goals is monitored using a combination of surveys, but principally using the secondary analysis of the Living Costs and Food Survey (LCFS), following the endorsement of the Working Group Report on Monitoring Scottish Dietary Targets who concluded that it was the most appropriate method for Scotland (Food Standards Agency in Scotland, 2004). Other surveys that collect data on dietary intake include the Scottish Health Survey (SHeS) (McLean et al., 2017) and the UK National Diet and Nutrition Survey (NDNS) (Bates et al., 2016, Bates et al., 2014b, Public Health England and Food Standards Agency, 2014, Roberts et al., 2018), however neither survey provides annual data suitable for monitoring the goals.

Secondary analysis of the LCFS, (known as the Expenditure and Food Survey (EFS) before 2008) has monitored trends in population food and nutrient intakes from 2001. Previous reports describe the monitoring of progress towards the SDTs and additional foods and drinks indicative of diet quality (further foods from the Scottish Diet report (Scottish Office, 1993)) from 2001-2006 (Barton et al., 2010), 2001 to 2009 (Barton and Wrieden, 2012) and energy density (Wrieden and Barton, 2011), and 2001-2012 (Wrieden and Barton, 2015). This current report updates previous reports, with the inclusion of data from 2013 to 2015, monitoring progress towards the 2013 Scottish Dietary Goals (which were the goals that were applicable for this time period). It also includes an update of consumption data, for 2001 to 2015 , of foods shown to be significant contributors to energy, fat, saturated fat, NMES and NSP in a further report by Barton and Wrieden (2015).

### 1.3 Monitoring Progress towards Preventing Overweight and Obesity

The prevalence of overweight and obesity in adults aged 16 years and over in Scotland rose from 62\% in 1995 to $65 \%$ in 2016, although the level has remained fairly constant since 2008 (McLean et al., 2017). Despite this, Scotland still has one of the highest prevalence rates of overweight and obesity in Europe (World Obesity Federation, 2018). Obesity increases the risk of chronic conditions such as type 2 diabetes, hypertension, cardiovascular disease, certain cancers and osteoarthritis(World Health Organisation, 2003).

In 2017, the Scottish Government consulted with a wide range of stakeholders regarding proposed actions to improve diet and physical activity in Scotland (Scottish Government, 2017a). These proposals were partly informed by experience of implementing the Obesity Route Map (Scottish Government, 2010). The route map outlined a range of preventative actions covering energy consumption, food product reformulation, portion sizes, stocking policies, pricing, packaging, and advertising with the aim to reduce the rising obesity levels in order to avoid the massive burden of health and social care costs. Progress towards these actions is monitored through a set of 16 indicators and associated desired outcomes, with this secondary analysis of the LCFS used to monitor the indicators of fat, saturated fat and NMES intake.

The importance of healthy weight and tackling obesity has been identified as a priority in the Government's Programme for Scotland (Scottish Government, 2017b). Therefore, the results presented in this report will continue to support work by Food Standards Scotland and the Scottish Government to facilitate improvements to the diet in Scotland to help reduce the burden of obesity and diet-related disease.

### 1.4 Purpose

The purpose of this work was to obtain robust estimates of food consumption and nutrient intakes for 2013 to 2015 in Scotland in order to monitor progress toward the 2013 Scottish Dietary Goals (which were the goals that were applicable for this time period) and any change in the consumption of additional foods and drinks indicative of diet quality. Results are presented for 2001 to 2015 for the population and by Scottish Index of Multiple Deprivation (SIMD) quintiles for 2013-2015. In addition, the main contributors to intakes of energy, fat, saturated fat, NMES and NSP intakes were explored in order to inform Food Standards Scotland and Scottish Government policy and further explain differences in the intake of some foods by deprivation which do not necessarily translate into differences in nutrient intakes.

## 2. Methodology

### 2.1 Monitoring Scottish Dietary Goals and additional foods and drinks indicative of diet quality

### 2.1.1. Overview

The methodology reported by Barton et al. (2010) and Wrieden et al. (2014) (summarised below) was used to calculate mean food consumption, nutrient intake and energy density from LCFS data for 2013 to 2015 in order that comparisons could be made with results from previous years. LCFS data for each year, in its raw form, was obtained from UK and the Office for National Statistics (ONS) (prior to it being made publically available on the UK Data Archive, University of Essex). Population average intakes of foods, nutrients and energy density relating to the 2013 Scottish Dietary Goals and additional foods and drinks indicative of diet quality, were estimated based on household purchases. Full details on the methodology can be found in Appendix 1, and the advantages and disadvantages of using data from the LCFS are provided in Appendix 2.

### 2.1.2 Coding Frames and Conversion Factors

The detailed coding frames (Appendices 3 and 4) used in this analysis were developed previously by Barton et al. (2010) and Wrieden and Barton (2011), for both household and eating out food purchases. They list foods/drinks (and codes) which form part of each food based dietary goal or food group of interest (Appendix 3) or are included within the food and milk method of calculating energy density (Appendix 4) and provide details of conversion factors applied to the food weights. Conversion factors were applied to food purchases to estimate the actual amount of each food that was consumed. They were applied (to each food code) to estimate the proportion of fruit, vegetable, meat etc. in a composite food; the proportion of food in a food grouping (where it bridges more than one food grouping); to convert a raw to cooked weight (where appropriate); and to account for the proportion of inedible waste. Estimates of edible waste for the UK population published by WRAP (2008) have been mapped by Defra to each of the food codes used in the LCFS (Appendix 5). Inedible waste (i.e. bone) was taken into account when calculating the conversion factor for each food code (Appendices 3 and 4).

### 2.1.3 Data Handling

Appendix 6 provides a flowchart which illustrates the data handling process for data from each year (in MS Access, MS Excel and SPSS), which were then merged in SPSS to obtain one working data file. Data on sampling strata and clusters, and SIMD quintiles were obtained from the UK ONS, with data on SIMD quintiles by postcode initially obtained from Scottish Neighbourhood Statistics and sent to ONS to link to anonymised case IDs.

In brief, for estimating food consumption, in MS Access the raw LCFS data was linked to a table constructed from the coding frame which listed each food grouping, each food within these groupings and the appropriate conversion and waste factors to be applied to the calculations. Household and eating out purchases for two weeks, minus waste, for each food code were multiplied by the appropriate conversion factor and summed by food grouping. This was then divided by the number of individuals in the household and divided by 14 to obtain
the mean daily consumption per person, except for oily fish consumption, which is expressed as a weekly intake.

For estimating nutrient intake, in MS Access, household purchase data minus waste for each food code was multiplied by the appropriate nutrient content per gram (annual nutrient databanks provided by Defra) to provide the nutrient intake per food. The food composition data included within this databank originates from the NDNS, with each of the Defra food codes having at least one NDNS composition code. Where more than one NDNS code was required to make up a food type from the EFS/LCFS, a weighted average nutrient composition was calculated based on market share estimates. The nutrient composition data was supplied to Defra by the FSA for 2001-2009 and by the Department of Health and Public Health England for 2010 onwards. Household, eating out and combined nutrient intakes for foods were then summed for each household. These were then divided by the number of individuals in the household and divided by 14 to obtain the mean daily intake per person for each nutrient. Energy density for food and milk was calculated using the methodology developed by Wrieden et al. (2014) and quintiles of energy density were calculated in SPSS by year (to negate any difference in energy density quintile over time).

Food and nutrient data were exported from MS Access to SPSS and merged with household variables as described in Appendix 1.

### 2.2 Contribution of foods to intakes of energy and selected nutrients

As per section 2.1.3, household purchase data over two weeks minus estimated waste (Appendix 5) for each food code was multiplied by the appropriate nutrient content per gram (provided by Defra) in MS Access to obtain the nutrient intake per food for each household. These intakes were then divided by the number of individuals in the household and divided by 14 to obtain the mean daily nutrient intake per person for each food. The food groupings described by (Barton and Wrieden, 2015) were used in the current analysis with the exception that it was decided that confectionery and sweet biscuits should be considered separately, therefore the current analysis was for 65 food groupings and 7 combined groups (Appendices 7 and 8). As this work considered foods as consumed, these food groupings are broad and are different to those used for the monitoring analysis in that they do not consider the different components of composite dishes / items. For example the 'total processed red meat' group includes the carbohydrate component for some items (e.g. pastry) and the 'fruit and vegetable' group does not include the vegetable component of composite dishes (e.g. Bolognese, pizza etc.). Mean daily intakes per person of each of the food groupings were calculated and the resultant data was exported to SPSS. In order to calculate mean population intakes it was also necessary to add information on zero intake for non-consumers of foods per household (as described by Barton et al., (2015)). The contribution that each food grouping made to energy, fat, saturated fat, NMES and NSP intake was then calculated.

### 2.3 Analysis of Data

Due to the multi-staged stratified sampling procedure of the LCFS, data were analysed using Descriptive Statistics and General Linear Models within the Complex Samples module of SPSS, version 25 (SPSS Inc., Chicago, IL, USA). Sampling of the EFS/LCFS is designed in such a way to ensure that the results are
representative of the population of the UK (Bulman et al., 2017) and each of the survey regions, of which Scotland is one. The data were weighted according to the sampling methodology (of the original data collected by ONS (Office for National Statistics, 2017) to reduce the effect of non-response bias and to ensure that data were representative of the population) in order that estimates obtained more accurately reflected that of the Scottish population and household composition. The weights were produced in two stages: firstly the data were weighted to compensate for non-response (sample-based weighting) and secondly the sample distribution was weighted so that it matched the population distribution in terms of region, age group and sex (population based weighting) (Department for Environment Food \& Rural Affairs (Defra), 2013). The weights were provided by Defra.

Linear associations between food consumption/ nutrient intake/ energy density and year or SIMD quintile were assessed by general linear modelling which was used to obtain estimates of the means with $95 \%$ confidence intervals ( $95 \% \mathrm{Cl}$ ) and associated p-values. Overall associations between food consumption/ nutrient intake/ energy density, and year or SIMD quintile were assessed by adjusted Wald tests. The adjusted Wald test was used within regression analyses to test whether the value for all years or SIMD categories were equal or whether there was at least one difference between year or SIMD quintile. P-values $\leq 0.01$ are highlighted in bold to indicate significance at the $1 \%$ level.

In addition, for the monitoring work, the Slope Index of Inequality (SII) was calculated as a measure of absolute inequality (ScotPHO, 2007) of food consumption and nutrient intake, i.e. the absolute difference between the least and most deprived individuals. The SII was derived by ranking each household by SIMD (within the 3 year period SIMD was investigated within i.e. 2001-2003, 2004-2006, 2007-2009, 2010-2012 and 2013-2015). The rank scores obtained were divided by the sample size (for the appropriate 3 year period) to obtain a value between 0 and 1 , weighted to the relative distribution across SIMD quintiles. Linear regression analysis (weighted least squares) of the mean intake within each SIMD quintile was used to calculate the SIls for each food / nutrient. The SII is the resulting regression (or slope) coefficient from the regression analysis. For interpretation purposes, the SII is the mean difference in intake between the hypothetically most deprived relative to the hypothetically least deprived person in the population (Shaw et al., 2007).

In order to compare a measure of inequality across populations or years, the relative index of inequality (RII) was calculated, which is the SII divided by the overall population mean food consumption or nutrient intake. This helps when making comparisons of the magnitude of the association between the same socio-economic position measures over time.

For both SII and RII, the underlying assumption is that there is a linear gradient across the deprivation variable. A positive SII indicates that consumption / intake is higher in the least deprived and a negative figure indicates that consumption / intake is greatest in the most deprived. Further detail is provided in Appendix 9.

## 3. Results

### 3.1 Monitoring Scottish Dietary Goals and additional foods and drinks indicative of diet quality

Results are presented as population per capita means (i.e. including consumers and non-consumers) for household and eating out foods combined, in g per day for foods and drinks with the exception of fish, which is expressed in g per week. Comparison is made against the 2013 Scottish Dietary Goals (where appropriate) as these were the goals that were applicable for the 2013-2015 data added in this report. P-values $\leq 0.01$ are highlighted in bold to indicate significance at the $1 \%$ level, although it should be noted that changes or differences that are statistically significant might not necessarily be nutritionally meaningful.

Mean food consumption and nutrient intakes relating to the Scottish Dietary Goals (Table 1) and additional foods, drinks and nutrients indicative of diet quality are presented in three year blocks from 2001-2003 through to 2013-2015. Data on individual years from 2001 through to 2015 is presented in Appendix 10 (see explanatory notes for further details on sampling years - pages xiii and xiv). Food consumption and nutrient intakes for Scotland are also presented for combined years' data from the LCFS by SIMD quintile. Data from 2013 to 2015 are combined and presented by quintiles of the SIMD distribution, with quintile 1 representing the most deprived fifth of the population and quintile 5 the least deprived. Results tables with data by SIMD quintile also provide SII and RII figures with $95 \%$ confidence intervals $(95 \% \mathrm{CI})$. Appendix 9 presents these figures for 2001-2003, 2004-2006, 2007-2009, 2010-2012 and 2013-2015 together to allow for a comparison to be made over time of absolute and relative differences.

### 3.1.1 Food Consumption Relating to the 2013 Scottish Dietary Goals

### 3.1.1.1 Food Consumption Relating to the Scottish Dietary Goals by Year

## Fruit and Vegetables

Between 2001-2003 and 2013-2015 there was no significant change in consumption of fruit and vegetables (including fruit and vegetable juices and baked beans). Mean consumption of fruit and vegetables for 20132015 was $258 \mathrm{~g} /$ day (Table 2). This equates to just over three portions per day and is considerably lower than the 2013 goal of at least 400 g or five portions per day. Inclusion of fruit juice increased fruit and vegetable consumption figures by the equivalent of half a portion per day but the proportion of fruit to fruit juice remained similar over the time period.

Mean fruit and vegetable consumption remains almost two portions below the '5 a day' population goal.

There was no significant increase in fruit and vegetable consumption over the 15-year period to 2015.

## Oil Rich Fish

The Scottish Dietary Goal for oil rich fish was not met by 2013-2015 and there was no significant change in consumption since 2001-2003. Mean consumption for both 2001-2003 and 2013-2015 was 29g/week (Table 2), which is considerably less than the goal of $140 \mathrm{~g} /$ week.

There was no significant change in oil rich fish consumption between 2001-2003 and 2013-2015.

## Total Red Meat

There has been a significant reduction in the consumption of total red meat since 2001-2003. Mean daily consumption of total red meat has decreased from 65 g in 2001-2003 to 56 g in 2013-2015 (Table 2) ( P -value for linear association $<0.001$ ). This was partly accounted for by a fall in processed red meat products (which includes the meat portion of sausages, meat pies, corned beef, burgers and pate and is a component of total red meat). It should be noted that the Scottish Dietary Goal of $\leq 70 \mathrm{~g}$ per day is based on intake calculated from the UK NDNS and not household purchase data. Due to methodological differences between surveys, the amounts presented in this report, although similar, should only be used to assess change over time rather than assessing progress against the absolute amount.
There was a significant reduction in total red meat consumption between 2001-2003 and 2013-2015.

The population is meeting the Scottish Dietary Goal for total red meat consumption.

Table 2: Mean Consumption ${ }^{1}$ of 2013 Scottish Dietary Goal Foods by Year, 2001 to 2015 - EFS / LCFS data ( $\mathrm{g} / \mathrm{person} / \mathrm{day}$ with the exception of fish: $\mathrm{g} / \mathrm{person} / \mathbf{w e e k}$ )

[^1]
### 3.1.1.2 Food Consumption Relating to the 2013 Scottish Dietary Goals by SIMD Quintile (2013-2015)

Fruit and Vegetables
Table 3 and Figure 1 show a clear gradient in fruit and vegetable consumption by SIMD quintile. In the most deprived quintile (Quintile 1), mean daily consumption was 201 g compared with 323 g in the least deprived quintile (Quintile 5) for 2013 to 2015. This linear trend was highly significant ( $\mathrm{P}<0.001$ ).

Two and a half portions per day of fruit and vegetables were consumed in the most deprived fifth of the population compared to four portions per day in the least deprived fifth.

## Oil Rich Fish

Consumption of oil-rich fish was highest in the least deprived quintile (Quintile 5) for 2013 to 2015, with a mean weekly consumption of 40 g compared to 20 g in the most deprived quintile (Quintile 1) (P-value for linear association <0.001) (Table 3, Figure 2).

Households in the most deprived fifth of the population were on average consuming half the amount of oil rich fish of those in the least deprived fifth.

## Total Red Meat

There was no significant difference in total red meat consumption by SIMD quintile (Table 3, Figure 3), with mean intakes in all quintiles meeting the 2013 Scottish Dietary Goal of $\leq 70 \mathrm{~g} /$ day.

There was no difference in mean total red meat consumption by SIMD quintile.

## Absolute and Relative Inequality

Analysis by SII and RII confirm the above differences by SIMD (for fruit and vegetables, oil rich fish and total red meat), in absolute and relative terms. Appendix 9 provides the results of the SII and RII analysis over time showing that there has been no significant change in inequalities and that absolute and relative inequalities in food intakes have not changed appreciably between 2001 and 2015. The magnitude of the inequalities is substantial for some foods, e.g. fruit and vegetables where the difference between the most and least deprived is the equivalent of one and a half portions per day.

Table 3: Mean Consumption ${ }^{1}$ of 2013 Scottish Dietary Goal Foods by SIMD Quintile, 2013 to 2015 Combined - LCFS data (g/person/day, with the exception of fish g/person/week)

${ }^{1}$ Meat portion only; 2013-2015 $P$ (linear association) $=0.134 ; P$ (overall association) $=0.117$

### 3.1.2 Nutrient Intake Relating to the 2013 Scottish Dietary Goals

There was little change in consumption of the Scottish Dietary Goal nutrients between 2001 and 2015, and none of the goals were met by 2015.

### 3.1.2.1 Nutrient Intake Relating to the 2013 Scottish Dietary Goals by Year Energy Density

Energy density, calculated from food and milk, has increased significantly between 2001-2003 and 2013-2015 ( P -value for linear association $=0.002$ ) (Table 4). The mean energy density for 2013-2015 was $175 \mathrm{kcal} / 100 \mathrm{~g}$, which is considerably higher than the 2013 Scottish Dietary Goal of $125 \mathrm{kcal} / 100 \mathrm{~g}$.

## Energy density has increased between 2001-2003 and 2013-2015.

## Total Fat and Saturated Fat

There has been no evidence of progress towards the 2013 Scottish Dietary Goal for total fat (average intake to reduce to no more than $35 \%$ food energy) (Table 4) with mean intakes increasing slightly, but not significantly, from $38.8 \%$ for 2001-2003 to $39.3 \%$ for 2013-2015. A significant reduction was found in the percentage of food energy from saturated fat ( P -value for linear association $=0.006$ ) (Table 4). However, the mean percentage of food energy contributed by saturated fat was $15.3 \%$ for 2013-2015, which is considerably higher than the 2013 goal of no more than $11 \%$ food energy.

There has been no significant change in total fat intakes between 2001-2003 and 2013-2015.

## Non-milk Extrinsic Sugars

A significant reduction over time was found for the percentage of food energy from non-milk extrinsic sugars (NMES) (Table 4). The mean percentage of food energy contributed by NMES fell from 15.7\% in 2001-2003 to $14.3 \%$ in 2013-2015. The overall decrease in the percentage of energy from NMES was highly significant (P-value for linear association <0.001), however it remains very high compared to the 2013 Scottish Dietary Goal of no more than $11 \%$ food energy.
Saturated fat and non-milk extrinsic sugar intakes (expressed as a percentage of food energy) have fallen slightly between 2001-2003 and 2013-2015 but still exceed population goals.

## Non-starch Polysaccharide

There has been no change in the mean intake of non-starch polysaccharide (NSP) between 2001-2003 and 2013-2015 (Table 4), with the mean intake remaining considerably below the 2013 Scottish Dietary Goal of 18g/day. Mean NSP intake was 12g/day for both 2001-2003 and 2013-2015.

## There has been no significant change in fibre intakes between 2001-2003 and 2013-2015

## Energy, Protein, Carbohydrate and Alcohol

Energy intake is not monitored using data from the LCFS, and is provided for comparison purposes only. A significant reduction over time was found for food energy intake (Table 5), with a mean intake in 2001-2003 of 2052kcal/day compared to 1889kcal/day in 2013-2015 (P-value for linear association <0.001). Protein, carbohydrate, total energy and alcohol intakes are not part of the 2013 Scottish Dietary Goals and are provided for comparison purposes only (Table 5).

### 3.1.2.2 Nutrient Intake Relating to the Scottish Dietary Goals by SIMD Quintile (2013-2015)

Energy Density
Energy density was lower in the least deprived quintile of SIMD (Quintile 5) at $167 \mathrm{kcal} / 100 \mathrm{~g}$, compared with $177 \mathrm{kcal} / 100 \mathrm{~g}$ in the most deprived quintile (Quintile 1) for 2013 to 2015 (Table 6, Figure 4), however this linear association with SIMD quintile was not statistically significant. Mean energy density in all quintiles of SIMD failed to meet the 2013 Scottish Dietary Goal.

## There was no difference in mean energy density by SIMD quintile.

## Total Fat and Saturated Fat

Table 6 and Figures 5 and 6 show that there was no statistical association between SIMD quintile and the percentage of food energy from total or saturated fat for 2013 to 2015.

## There was no difference in mean total or saturated fat intake by SIMD quintile.

## Non-Milk Extrinsic Sugars

NMES intake was lower in the least deprived quintile (Quintile 5) at $14.1 \%$ of food energy, compared with $15.7 \%$ in the most deprived quintile (Quintile 1) for 2013 to 2015 (Table 6, Figure 7), however this association with SIMD quintile was not statistically significant. Mean intakes in the least deprived quintile of SIMD still failed to meet the 2013 Scottish Dietary Goal.

## There was no difference in mean NMES intake by SIMD quintile.

## Non-Starch Polysaccharide

NSP intake was significantly higher in the least deprived quintile of SIMD (Quintile 5) at $13 \mathrm{~g} /$ day compared with 11g/day in the most deprived quintile (Quintile 1) for 2013 to 2015 ( P -value for linear association <0.001) (Table 6, Figure 8). However mean intakes in all quintiles of SIMD failed to meet the 2013 Scottish Dietary Goal.

Non-starch polysaccharide intake was highest in the least deprived fifth of the population, but failed to meet the goal in all SIMD quintiles.

## Energy, Protein, Carbohydrate and Alcohol

Table 7 shows that there was no statistically significant linear association between food energy, protein, carbohydrate, total energy and alcohol intake and SIMD quintile for 2013 to 2015.

## Absolute and Relative Inequality

Analysis by SII and RII confirm the above differences by SIMD in absolute and relative terms. Appendix 9 provides the results of the SII and RII analysis over time showing that there has been no significant change in inequalities from 2001 to 2015.

### 3.1.3 Consumption of Additional Foods and Drinks Indicative of Diet Quality

### 3.1.3.1 Food Consumption by Year

Bread
Mean total daily bread consumption decreased significantly over the period 2001-2003 to 2013-2015 (from 107 g to 83 g , P -value for linear association $<0.001$ ) (Table 8). This was accounted for by a steady decrease in white bread. However, intakes of brown/wholemeal bread have remained fairly constant with a mean intake for 2013-2015 of 18g/day. By 2013-2015, $21.7 \%$ of bread consumed was brown/wholemeal compared to 16.8\% for 2001-2003.

## Breakfast Cereal

Mean high fibre and total breakfast cereal consumption remained fairly constant from 2001-2003 to 20132015. The mean intake for 2013-2015 was $12 \mathrm{~g} /$ day and 20 g /day respectively (Table 8).

Cakes, Sweet Biscuits and Pastries; Sugar and Preserves; Confectionery and Ice Cream and Dairy Desserts Mean consumption of cakes, sweet biscuits and pastries; sugar and preserves; confectionery; and ice cream and dairy desserts have remained fairly constant between 2001-2003 and 2013-2015 with mean intakes for 2013-2015 of 38, 16, 21 and $33 \mathrm{~g} /$ day respectively (Table 8).

## Soft Drinks

The trends in consumption of sugar-containing soft drinks mirrored that of NMES intake (Table 8, Appendix 10 Table C and Figure I). Overall, sugar-containing soft drink consumption decreased significantly from $245 \mathrm{~g} /$ day for 2001-2003 to $156 \mathrm{~g} /$ day for 2013-2015 (P-value for linear trend $<0.001$ ). In contrast, the mean intake of sugar free soft drinks increased significantly from 104g/day for 2001-2003 to 133g/day for 2013-2015 ( P -value for linear association $<0.001$ ).

## Processed Red Meat Products

Bacon and ham consumption has remained constant over the period of 2001-2003 to 2013-2015 (Table 9), however consumption of other processed red meat products decreased significantly over the same time period from 29 to $26 \mathrm{~g} /$ day ( P -value for linear association $=0.001$ ) (this includes the meat content of savoury pies). Savoury meat pie consumption (based on total pie weight) decreased significantly from 10g/day for 2001-2003 to $8.7 \mathrm{~g} /$ day for 2013-2015 ( P -value for linear association $=0.003$ ).

## Dairy Products and Fat

Mean butter and soft margarine intake increased from 5.8 and $1.3 \mathrm{~g} /$ day respectively for 2001-2003 to 7.7 and $1.7 \mathrm{~g} /$ day for 2013-2015 (P-values for linear association $<0.001$ and 0.007 ). Over the same time period there was a significant reduction in mean low fat spread consumption from 8.9 to $5.0 \mathrm{~g} /$ day ( P -value for linear association $<0.001$ ) (Table 9), such that there was a reduction in total spread consumption (P-value for linear association 0.022). There was no significant change to cooking oil or cheese consumption over time, but there was an increase in mean cream consumption from 2.4 to $3.6 \mathrm{~g} /$ day ( P -value for linear association <0.001). Mean total daily milk consumption decreased from 248 g for 2001-2003 to 197 g for 2013-2015 (P-value for linear association <0.001). This was caused by a decrease in mean whole milk consumption from 89 to 38 g/day (P-value for linear association <0.001) (Table 9).

## White Fish

Mean white fish consumption has decreased significantly from 92g/week for 2001-2003 to 75g/week for 20132015 (P-value for linear association <0.001) (Table 9).

Potatoes, Nuts and Savoury Snacks
There was a significant decrease in fresh potato consumption between 2001-2003 and 2013-2015 (P-value for linear association <0.001), with a mean consumption for 2013-2015 of $40 \mathrm{~g} /$ day compared with a mean consumption for 2001-2003 of 60g/day. Processed potato (e.g. chips) and savoury snack consumption fluctuated between 2001-2003 and 2013-2015, with no statistically significant linear association. Mean nut consumption increased from 2.0g/day for 2001-2003 to 4.0g/day for 2013-2015 (P-value for linear association <0.001) (Table 9).

Table 8: Mean Consumption ${ }^{1}$ of Additional Foods and Drinks Indicative of Diet Quality by Year (Table A), 2001 to 2015 - EFS / LCF data (g/person/day)
$\left.\begin{array}{l|c|c|c|c|c|c}\hline \text { Food }{ }^{2} & 2001-2003 & 2004-2006^{3} & 2007-2009 & 2010-2012 & 2013-2015 \\ \text { Mean }\end{array} \begin{array}{c}\text { P-value for } \\ \text { Linear } \\ \text { Association }\end{array} \begin{array}{c}\text { P-value for } \\ \text { Associallion }\end{array}\right)$
${ }^{1}$ Household and eating out consumption combined; ${ }^{2}$ See appendices $1 \& 3$ for methodology; ${ }^{3}$ From 2006 the EFS moved from a financial year to a calendar year basis. As a consequence of this the January to March 2006 data are duplicated in the 2004-2006 results; ${ }^{4}$ The results are weighted to the Scottish population - the number provided is approximately $1000^{\text {th }}$ of the Scottish population

### 3.1.3.2 Food Consumption by SIMD

Bread
There was no significant association between total bread consumption and SIMD quintile for 2013 to 2015 (Table 10). Consumption of brown/wholemeal bread was highest in the least deprived quintile of SIMD (Quintile 5) at $24 \mathrm{~g} /$ day compared to $16 \mathrm{~g} /$ day in the most deprived quintile (Quintile 1) for 2013 to 2015 (P-value for linear association $=0.003$ ) $($ Table 10 $)$.

## Breakfast Cereals

Consumption of high fibre breakfast cereal and total breakfast cereal was highest in the least deprived quintile of SIMD (Quintile 5), at 15 and $25 \mathrm{~g} /$ day respectively compared to 7.1 and $16 \mathrm{~g} /$ day in the most deprived quintile (Quintile 1) for 2013 to 2015 ( P -values for linear association <0.001) (Table 10).

Cakes, Sweet Biscuits and Pastries; Sugar and Preserves; Confectionery and Ice Cream and Dairy Desserts There was no significant association between SIMD quintile and cakes, sweet biscuits and pastries; sweet biscuits; ice cream and dairy desserts; or confectionery for 2013 to 2015 (Table 10).

There was no significant association between total soft drink or sugar free soft drink consumption and SIMD quintile for 2013 to 2015 (Table 10). However, consumption of sugar containing soft drinks was lowest in the least deprived quintile of SIMD (Quintile 5) at $172 \mathrm{~g} /$ day compared to $263 \mathrm{~g} /$ day in the most deprived quintile (Quintile 1) for 2013 to 2015 (P-value for linear association = 0.006) (Table 10 and Figure 9). However, the reduction over time in soft drink consumption appears to be greater in the more deprived quintiles (Figure 18).

## Processed Red Meat Products

There was no statistical association between consumption of bacon and ham and SIMD quintile for 2013 to 2015 (Table 11). However, a statistically significant association was found with other processed red meat products, with consumption higher in the most deprived quintile (Quintile 1) at 33g/day compared to $23 \mathrm{~g} /$ day in the least deprived quintile (Quintile 5) for 2013 to 2015 (P-value for linear association $=0.002$ ) (this includes the meat content of savoury pies). A significant association between SIMD quintile and savoury meat pies (based on total pie weight) was found, with an intake of $12 \mathrm{~g} /$ day in the most deprived quintile compared to $7.9 \mathrm{~g} /$ day in the least deprived quintile for 2013 to 2015 ( $P$-value for linear association $=0.002$ ) (Table 11).

## Dairy Products and Fat

Mean consumption of whole milk was more than double in the most deprived SIMD quintile (Quintile 1) compared to the least deprived quintile (Quintile 5), ( $88 \mathrm{~g} /$ day compared to $39 \mathrm{~g} /$ day) for 2013 to 2015 (P-value for linear association $<0.001$ ) (Table 11). The least deprived quintile of SIMD (Quintile 5) had significantly higher intakes compared to the most deprived quintile (Quintile 1) of skimmed milk ( $18 \mathrm{~g} / \mathrm{day}$ compared to $10 \mathrm{~g} /$ day), cheese ( $17 \mathrm{~g} /$ day compared to $12 \mathrm{~g} /$ day), and cream ( $4.5 \mathrm{~g} / \mathrm{day}$ compared to $1.5 \mathrm{~g} / \mathrm{day}$ ) (P-values for linear association $=0.010,0.004$ and $<0.001$ respectively $)($ Table 11 $)$.

## White Fish

Consumption of white fish was highest in the least deprived quintile of SIMD (Quintile 5) at $101 \mathrm{~g} / \mathrm{week}$, compared to $70 \mathrm{~g} /$ week in the most deprived quintile (Quintile 1) for 2013 to 2015 (P-value for linear association <0.001) (Table 11).

## Potatoes, Nuts and Savoury Snacks

No significant association with SIMD quintile was found for consumption of fresh potatoes, processed potatoes, or savoury snacks for 2013 to 2015, however a significant association was found with consumption of nuts (Table 11). Mean nut consumption was $4.2 \mathrm{~g} / \mathrm{day}$ in the least deprived quintile (Quintile 5) compared to $1.9 \mathrm{~g} /$ day in the most deprived quintile (Quintile 1) for 2013 to 2015 (P-value for linear association <0.001).

## Absolute and Relative Inequality

Analysis by SII and RII confirm the above differences by SIMD in absolute and relative terms. Appendix 9 provides the results for the SII and RII analysis for food consumption over time with regards to deprivation showing that there has been no significant change in inequalities from 2001 to 2015 for the majority of foods / drinks and that absolute and relative inequalities in food/nutrient intakes have not changed appreciably between 2001 and 2015.

### 3.2 Contribution of Foods to Intakes of Energy, Fat, Saturated Fat, NMES and Fibre

### 3.2.1 Differences in Contributing Foods over Time

Results are presented for food groupings (foods / drinks within these food groupings are presented in Appendix 8), which contribute more than $1 \%$ of energy, fat, saturated fat, NMES and NSP. Results are provided for population data (i.e. includes consumers and non-consumers) for the contribution of each food grouping to the total nutrient intake for energy in kcal, and for fat, saturated fat, NMES and NSP in grams. The tables presenting results for 2001-2003 to 2013-2015 have been ordered in descending order for the highest overall contributor of energy, fat, saturated fat, NMES and NSP, for 2013-2015. The tables also provide results on percentage contribution to household and eating out consumption for time periods 2013-2015. P-values were calculated for linear and overall association over time of the contributing amount in kcal or g rather than the \% contribution, and $p$-values $\leq 0.01$ are highlighted in bold to indicate significance at the $1 \%$ level.

## Contribution to Energy Intake

As presented in Table 5, mean food energy intakes reduced significantly between 2001-2003 and 2013-2015 from $2052 \mathrm{kcal} /$ day to $1889 \mathrm{kcal} /$ day respectively ( $\mathrm{P}<0.001$ ). For 2013-2015, $88 \%$ of energy intake was from household food purchases and $12 \%$ was from eating out purchases. The proportion of energy obtained from household purchases has increased steadily from $85 \%$ for 2001-2003 while the proportion of energy obtained from eating out purchases has reduced steadily from 15\% for 2001-2003.

Table 12 shows that the highest contributors to energy were total processed red meat (7.5\%), bread and rolls (6.7\%), unclassified foods ${ }^{1}$ ( $5.9 \%$ ), sweet biscuits ( $5.3 \%$ ) and total milk ( $5.3 \%$ ). With the exception of unclassified foods ${ }^{1}$ and sandwiches, household consumption provided the greatest proportion of total energy for each of the food groupings. The highest contributors to total energy from eating out foods and drinks were unclassified foods ${ }^{1}$ (3.9\%), sandwiches (1.0\%), alcoholic drinks ( $0.8 \%$ ), total processed red meat ( $0.7 \%$ ), processed potatoes $(0.7 \%)$ and sugar containing soft drinks $(0.6 \%)$. On the whole, foods for which there was a significant decrease in the absolute amount over time also had a decreasing percentage contribution to energy over time. These foods were bread and rolls, total milk, sugar containing soft drinks, unprocessed red meat, sugar and sandwiches. Conversely the contribution from savoury sauces and dressings, other baked goods, ready meals and pizza to energy increased over the five 3 year periods (Table 12).

## Contribution to Fat Intake

Table 13 shows that the highest contributors to fat were total spreading fats ( $12.4 \%$ ), total processed red meat (12.0\%), unclassified foods ${ }^{1}$ ( $6.9 \%$ ), cooking oil ( $6.8 \%$ ), sweet biscuits ( $5.9 \%$ ), total milk ( $5.2 \%$ ) and total cheese (5.1\%). With the exception of unclassified foods ${ }^{1}$, sandwiches and eating out main meal components, household consumption provided the greatest proportion of fat for each of the food groupings. The highest contributors to fat from eating out foods and drinks were unclassified foods ${ }^{1}$ (4.9\%), sandwiches (1.2\%), eating out main meal components (1.2\%), total processed red meat (1.0\%), processed potatoes ( $0.7 \%$ ), and cakes, pastries and puddings $(0.5 \%)$. On the whole, foods for which there was a significant decrease in the absolute amount over time also had a decreasing percentage contribution to energy over time. These foods were total milk, crisps and savoury snacks unprocessed red meat, sandwiches, bread and rolls, and eggs. In contrast,

[^4]contribution from savoury sauces and dressings, ready meals, nuts, cream, pizza, and total breakfast cereal increased over the five 3 year periods (Table 13).

## Contribution to Saturated Fat Intake

Table 14 shows that the highest contributors to saturated fat were total spreading fats ( $16.0 \%$ ), total processed red meat ( $12.0 \%$ ), total milk ( $8.5 \%$ ), total cheese ( $8.4 \%$ ), sweet biscuits ( $7.7 \%$ ), total confectionery ( $6.3 \%$ ) and unclassified foods ${ }^{1}(5.8 \%)$. With the exception of unclassified foods ${ }^{1}$ and sandwiches, household consumption provided the greatest proportion of saturated fat for each of the food groupings. The highest contributors to saturated fat from eating out foods and drinks were unclassified foods ${ }^{1}$ (3.5\%), total processed red meat (1.0\%), sandwiches ( $0.9 \%$ ), and cakes, pastries and puddings ( $0.5 \%$ ). On the whole, foods for which there was a significant decrease in the absolute amount over time also had a decreasing percentage contribution to energy over time. These foods were total milk, unprocessed red meat, crisps and savoury snacks, sandwiches, processed potatoes and eggs. In contrast, contribution from cream, pizza and nuts increased (Table 14).

## Contribution to NMES Intake

Table 15 shows that the highest contributors to NMES were sugar containing soft drinks (20.8\%), total confectionery (17.9\%), sugar (13.3\%), sweet biscuits ( $8.0 \%$ ) total fruit and vegetables ( $6.8 \%$ ), cakes, pastries and puddings (6.2\%) and ice cream and dairy desserts (5.1\%). For all food groupings, except alcoholic drinks, household consumption provided the greatest proportion of NMES. The highest contributors to NMES from eating out foods and drinks were sugar-containing soft drinks (3.8\%), alcoholic drinks (1.5\%), total confectionery $(0.9 \%)$ and cakes, pastries and puddings ( $0.6 \%$ ). Sugar containing soft drinks contributed an average of 22.5 g ( $25.8 \%$ of total NMES) in 2001-2003 but this decreased to $14.9 \mathrm{~g}(20.8 \%)$ by 2013-2015. The percentage contribution from sugar, and alcoholic drinks decreased between 2001-2003 and 2013-2015 and percentage contribution from ice cream and dairy desserts increased (Table 15).

## Contribution to NSP Intake

Table 16 shows that the highest contributors to NSP were total fruit and vegetables ( $24.1 \%$ ), bread and rolls (13.5\%), total breakfast cereals (9.7\%), unclassified foods ${ }^{1}$ ( $9.2 \%$ ) and processed potatoes (5.2\%). With the exception of unclassified foods ${ }^{1}$, eating out main meal components and sandwiches, household consumption provided the greatest proportion of NSP for each of the food groupings. The highest contributors to NSP from eating out foods and drinks were unclassified foods ${ }^{1}$ ( $6.5 \%$ ), eating out main meal component (1.4\%), processed potatoes (1.2\%), sandwiches ( $0.9 \%$ ) and fruit and vegetables ( $0.7 \%$ ). A significant decrease in the contribution of bread and rolls, crisps and savoury snacks, potatoes, and sandwiches to NSP was seen in absolute terms, which was reflected in a decreasing percentage contributed. However, a small significant increase in the contribution from pasta, rice and noodles, other baked goods (i.e. items such as non-standard breads such as garlic bread, teacakes etc.), total confectionery, cakes pastries and puddings, ready meals, savoury sauces and dressings, nuts, and savoury biscuits was observed (Table 16).

[^5]Table 12: Mean contribution of foods providing more than 1\% of energy (2001-2015 data)

### 3.2.2 Differences in Contributing Foods over Time by SIMD

Tables 17-21 present the contribution of foods to intakes of energy, fat, saturated fat, NMES and NSP by SIMD quintile for 2013 to 2015. The tables have been arranged in descending order of the greatest absolute difference between SIMD quintile 1 and SIMD quintile 5 for energy, fat, saturated fat, NMES and NSP. A pragmatic decision was taken to present only the results for food groupings where there was both a significant difference for linear association at $\mathrm{p}<0.05$ and an absolute difference between SIMD quintile 1 and SIMD quintile 5 which was greater than or equal to 10 kcal or 0.1 g . Percentage contributions presented are based on the total intake for the SIMD quintile rather than that of the overall population. P -values were calculated for linear and overall association with the contributing amount in kcal or g rather than the \% contribution, with p values $\leq 0.01$ highlighted in bold to indicate significance at the $1 \%$ level. The absolute difference column is the absolute difference between the most and the least deprived quintile and is a simple measure of inequality. A positive figure shows that contribution of the food grouping is greater in the most deprived quintile and a negative figure shows that contribution of the food grouping is greater in the least deprived quintile.

## Energy

Table 17 shows that the foods, contributing to energy intake, for which there were absolute differences greater than or equal to 25 kcal between SIMD quintiles were total processed red meat, cooking oil, and bread and rolls (consumed more in the most deprived) and alcoholic drinks, total fruit and vegetables, and total breakfast cereals (consumed more in the least deprived).

## Fat

Table 18 shows that the foods, contributing to fat intake, for which there were absolute differences greater than or equal to one gram between SIMD quintiles were total processed red meat, cooking oil and whole milk (consumed more in the most deprived) and cream, butter, and nuts (consumed more in the least deprived).

## Saturated Fat

Table 19 shows that the foods, contributing to saturated fat intake, for which there were absolute differences greater than or equal to 0.5 grams between SIMD quintiles were total processed red meat and whole milk (consumed more in the most deprived) and cream, butter, and total cheese (consumed more in the least deprived).

## NMES

Table 20 shows that the foods, contributing to NMES intake, for which there were absolute differences greater than or equal to 0.5 grams between SIMD quintiles were sugar containing soft drinks (consumed more in the most deprived) and total fruit and vegetables; jam, marmalade honey and sweet spreads; cakes pastries and puddings; alcoholic drinks; yoghurt and fromage frais; and wholegrain/high fibre breakfast cereal (consumed more in the least deprived). It should be noted that sugar containing soft drinks contributed 6.6 g more NMES in the most deprived than in the least deprived.

## NSP

Table 21 shows that the foods, contributing to NSP intake, for which there were absolute differences greater than or equal to 0.5 grams between SIMD quintiles were total fruit and vegetables and total breakfast cereal. They contributed the majority of the additional NSP consumed by the least deprived compared to the most deprived and as such fruit and vegetables and breakfast cereals that are high in fibre and low in NMES continue to be two key food groupings to be targeted in healthy eating messages to consumers and policy makers.

Table 17: Mean contribution to energy from selected foods ${ }^{1}$ by SIMD (LCFS Household and Eating Out Data for 2013 to 2015 combined)

## 4. Discussion

Monitoring of Scottish Dietary Goals and Additional Foods and Drinks Indicative of Diet Quality Estimates of mean food consumption and nutrient intake for Scotland, calculated using the household and eating out data from LCFS purchase data, and described previously (Barton and Wrieden, 2012, Barton et al., 2010, Wrieden and Barton, 2011, Wrieden and Barton, 2015) were updated by the addition of the years 2013, 2014 and 2015 to give trend data from 2001 through to 2015; this has been related to the Scottish Dietary Goals. This is currently the only method of monitoring the complete diet over time in Scotland. Advantages and disadvantages of using the LCFS to estimate food consumption and nutrient intake are presented in Appendix 2.

A summary of the results for the goals measured here are presented in Table 22. Although there have been fluctuations over the 15 years, little change was found in intakes of foods and nutrients between 2001 and 2015.

Table 22: Mean food and nutrient intakes in relation to the Scottish Dietary Goals from 2001 to 2015

| Food / Nutrient | Scottish Dietary Goal | $\begin{aligned} & 2001- \\ & 2003 \end{aligned}$ | $\begin{aligned} & 2013- \\ & 2015 \end{aligned}$ | $\begin{gathered} \text { Change } \\ \text { between 2001- } \\ 2003 \text { and } \\ 2013-2015^{1} \end{gathered}$ | Highest consumption by SIMD in 2013-2015 ${ }^{1,2}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Energy density (kcal/100g) | Average energy density of the diet to be lowered to 125 $\mathrm{kcal} / 100 \mathrm{~g}$ | 171 | 175 | $\uparrow$ | No Difference |
| Fruit and Vegetables (g/day) | At least 5 portions per person per day (> $400 \mathrm{~g} /$ day) | 256 | 258 | No Change | Least Deprived |
| Oil rich fish (g/week) | Increase to one portion per person (140g) per week | 29 | 29 | No Change | Least Deprived |
| Red Meat (g/day) | Average intake of red and processed meat to be pegged at around 70 g per person per day | 65 | 56 | $\downarrow$ | No Difference |
| Fat <br> (\% food energy) | $\leq 35 \%$ food energy | 38.8 | 39.3 | No Change | No Difference |
| Saturated Fat <br> (\% food energy) | $\leq 11 \%$ of food energy | 15.6 | 15.3 | $\downarrow$ | No Difference |
| Sugar <br> (\% food energy) | NMES ${ }^{3}$ to reduce to less than $11 \%$ of food energy in children and adults | 15.7 | 14.3 | $\downarrow$ | No Difference |
| Fibre (g/day) | Increase in average consumption of fibre ${ }^{4}$ to $18 \mathrm{~g} /$ day | 12 | 12 | No Change | Least Deprived |

[^7]Results from the LCFS suggest lack of progress towards the Scottish Dietary Goals. Little or no change was found in the trends of consumption of the food-based goals over the period 2001-2015. The small, but statistically significant, increase in mean consumption of fruit and vegetables, found in the 10-year period from 2001 to 2010 stalled, with mean consumption for 2013-2015 being similar to that for 20012003. Mean fruit and vegetable consumption remains almost 2 portions below the population target of 5 portions per day. No change has been found in oil rich fish consumption. Red and processed meat
consumption reduced significantly between 2001-2003 and 2013-2015 with mean consumption meeting the goals. There were significant associations between deprivation level (measured using SIMD quintile) for fruit and vegetables, and oily fish, with consumption being greatest in the least deprived, however still well below the goals.

The mean energy density of the diet increased significantly between 2001-2003 and 2013-2015. Intakes of fat as a percentage of food energy for 2013-2015 were similar to those for 2001-2003, however a significant decrease was found for saturated fat when observing the trend between 2001-2003 and 2013-2015 despite increases in some saturated fat containing foods such as butter and cream. The significant decrease in the percentage of energy from NMES observed in previous reports continued to 2013-2015; this was in line with the significant reduction in sugar-containing soft drink consumption. The observation that sugar-containing soft drink consumption mirrored the trend in NMES is important, as a key part of strategies to reduce the prevalence of obesity is reducing consumption of sugar-containing soft drinks (Scottish Government, 2017a). No association was found between intakes of fat, saturated fat or NMES and deprivation level, and intakes remain well above the Scottish Dietary Goals. Intakes of NSP remain unchanged since 2001-2003, with intakes higher in the least deprived, but still considerably below the goals. This finding is not surprising given the higher intakes of fruit and vegetables, brown/wholemeal bread and high fibre breakfast cereal in the least deprived.

Discretionary foods that are high in sugar and fat, namely sweet biscuits; confectionery; crisps and savoury snacks; cakes, pastries and puddings; and sugar sweetened beverages are significant contributors to energy in the diet. In the current analysis, these five food groupings contributed almost $20 \%$ of energy, fat and saturated fat intakes and more than $50 \%$ of NMES intake as is shown in Table 23. In the recently revised Eatwell Guide (Public Health England, 2016) discretionary foods/drinks were excluded in order to highlight that these foods/drinks are not needed in the diet.

Table 23: Mean contribution of selected discretionary foods and drinks to energy, fat, saturated fat and NMES intake in 2013-2015 (intake (percentage) per person per day)

|  | Weight <br> $\mathbf{g}$ | Energy <br> $\mathbf{k c a l}(\%)$ | Fat <br> $\mathbf{g ~ ( \% )}$ | Saturated Fat <br> $\mathbf{g ~ ( \% ) ~}$ | NMES <br> $\mathbf{g ~ ( \% ) ~}$ |
| :--- | :---: | :---: | :---: | :---: | :---: |
| Sweet Biscuits | 21.6 | $103(5.3)$ | $4.9(5.9)$ | $2.5(7.7)$ | $5.7(8.0)$ |
| Total Confectionery | 21.2 | $92.2(4.7)$ | $3.7(4.5)$ | $2.0(6.3)$ | $12.8(17.9)$ |
| Crisps and Savoury Snacks | 13.4 | $67.1(3.4)$ | $3.8(4.5)$ | $0.5(1.6)$ | $0.02(0.02)$ |
| Cakes, Pastries and Puddings | 16.5 | $59.7(3.1)$ | $2.8(3.3)$ | $1.2(3.7)$ | $4.4(6.2)$ |
| Sugar Containing Soft Drinks | 156 | $57.0(2.9)$ | Nil | Nil | $14.9(20.8)$ |
| Total |  | $379(19.4)$ | $15.2(18.2)$ | $6.2(19.3)$ | $37.8(52.9)$ |

## Comparison with the National Diet and Nutrition Survey

Unlike NDNS data for 2008/09-2011/12 (Bates et al., 2014a) results from the NDNS for 2012/132013/14 (years 5 and 6) (Bates et al., 2016) and 2014/15-15/16 (Bates et al., 2016, Bates et al., 2014b, Public Health England and Food Standards Agency, 2014, Roberts et al., 2018) are not available separately for Scotland as there was no boosted sample for Scotland for these years. Therefore, any comparison against recent NDNS results has to be made against UK data. Despite differences in the methods used to collect this data, figures relevant to the food based Scottish Dietary Goals are comparable given the proportion of the different age groups in the population - see summary Table 24
of key measures from both surveys related to the goals. Possible reasons for the differences in percentage of food energy from the macronutrients presented have been discussed previously (Barton and Wrieden, 2012, Barton et al., 2010, Wrieden and Barton, 2011, Wrieden and Barton, 2015).

Table 24: Comparison of mean food/nutrient intakes in relation to the 2013 Scottish Dietary Goals between LCFS 2013-2015 and 19-64y NDNS 2012/13-2013/14 and 2014/15-2015/16

| Food / Nutrient | Scottish Dietary Goal (SDG) | LCFS 2013-2015 |  | $\begin{gathered} \hline \text { NDNS 2012/13- } \\ 2013 / 14 \end{gathered}$ |  | NDNS 2014/152015/16 |  |

| Sugar <br> (\% food energy) | NMES to reduce to less than $11 \%$ of food energy in children and adults | 14.3 | Goal not met | 12.3 | Goal not met | 12.1* | Goal not met |
| Fibre (g/day) | Increase in average consumption of fibre to $18 \mathrm{~g} /$ day | 12 | Goal not met | 14.0 | Goal not met | 14.6** | Goal not met |

*Calculated from free sugar figure; ** Calculated from AOAC figure
Comparison of earlier NDNS Scottish data (2008/09-2011/12) (Bates et al., 2014a) with 2013-2015 LCFS data found similar food consumption patterns when comparing the two sets of data in relation to SIMD, with higher intakes of fruit and vegetables and oil rich fish in the least deprived quintiles and little difference in total red meat consumption. Results in relation to fat and saturated fat intake by SIMD showed a similar trend in both surveys, with no difference between levels of deprivation. However the percentage of energy from NMES was lower, and fibre (in terms of $g$ of NSP) was higher, in the least deprived quintiles in both the NDNS (except for NMES in children) and the LCFS.

Despite some similarities being found in food consumption and nutrient intake between the two surveys, it must be appreciated that that the LCFS results are based on purchase data and are expressed per capita, i.e. are an average of all ages, so comparison of the results with other studies should be carried out with caution. In addition, the figures for waste used to adjust the purchase data are from a UK WRAP survey of 2008 (Waste and Resource Action Programme Survey (WRAP), 2008) and do not account for reductions in waste over recent years (WRAP, 2014). WRAP waste figures for Scotland were published in 2009 (WRAP Scotland, 2009), but these could not be used in the current analysis as data was not available as a percentage of individual foods/food groups, and therefore no mapping to Defra food codes could be carried out using this data. Nevertheless, the fact that the LCFS provides a continuous survey of a representative sample of households in Scotland allows both comparison to be
made over time and the ability to consider any inconsistencies in the data, enabling a clearer assessment to be made of any dietary change.

## Future monitoring of the Scottish Dietary Goals

The Scottish Dietary Goals were revised in 2016 (Scottish Government, 2016), in order to reflect recommendations on total carbohydrate, sugar and fibre intakes from the Scientific Advisory Committee on Nutrition (SACN) published in 2015 (Scientific Advisory Committee on Nutrition (SACN), 2015). The recommended intake of sugar has halved, and the recommended intake of fibre has increased, and the terminology for sugar and fibre have both been revised. An additional 2016 goal specifies that total carbohydrate should "be maintained at an average population intake of approximately $50 \%$ of total dietary energy", with the term "total dietary energy" referring to the energy provided by protein, carbohydrate, fat and alcohol. This suggests an increase in total carbohydrate from the previous dietary reference value of a population average intake of $47 \%$ total energy ( $50 \%$ food energy) (Department of Health, 1991).

The 2013 Scottish Dietary Goals for "average intake of NMES to reduce to less than $11 \%$ of food energy in children and adults" has been replaced with the 2016 goal for "average intake of free sugars not to exceed $5 \%$ of total energy in adults and children over 2 years". Replacing the term "NMES" with "free sugars" will result in a slightly lower mean intake since NMES includes $50 \%$ of the fruit sugars from canned, dried or stewed fruit, and free sugars includes none (Scientific Advisory Committee on Nutrition (SACN), 2015). Nevertheless, current free sugar intakes are likely still to be more than twice the recommended intake, based on findings from the current report. In order to monitor the 2016 goal for free sugars, food composition databases will need to be updated.

The 2016 Scottish Dietary Goals specify that fibre be measured using the AOAC method rather than the Englyst method which measures NSP only, and that average intake of AOAC fibre should be $30 \mathrm{~g} /$ day in adults. This goal represents an increase in the recommended fibre intake, since the 2013 goal of $18 \mathrm{~g} /$ day for NSP equates to around $23-24 \mathrm{~g} /$ day of AOAC fibre. In order to allow monitoring of this goal, new analyses of foods and drinks should ideally be carried out to ensure that AOAC fibre data are available for key contributing food groups, as AOAC fibre data is incomplete in the current food composition tables.

## Conclusion

In summary, there was little progress towards meeting the Scottish Dietary Goals over the period 2001 to 2015; this was apparent even within the lowest deprivation quintiles. Despite evidence of progress towards the goal for fruit and vegetables up to 2010, by 2015 this trend was no longer evident. A slight but significant decreasing trend in the percentage of energy from NMES and saturated fat was apparent, but mean intakes still exceed the goals. The goal for total red and processed meat intake was met, with no difference in consumption between levels of deprivation. It is of concern that the energy density of the diet is increasing rather than reducing, and that foods targeted for increased consumption (fruit and vegetables, and oily fish) were significantly lower in the most deprived groups of the population.

However, no evidence was found to suggest that the gap between the most and least deprived is increasing, with the same very small improvements being found across all quintiles of SIMD. This work continues to be an important part of Food Standards Scotland's dietary surveillance programme.

## Appendix 1: Further Detail on Methodology of Monitoring Work The Living Costs and Food Survey / Expenditure and Food Survey

The Living Costs and Food Survey (LCFS) (before 2008 known as the Expenditure and Food Survey (EFS)) is a continuous survey of households in the UK commissioned jointly by the Office for National Statistics (ONS) and the Department for Environment and Rural Affairs (Defra). The LCFS is an annual household budget survey designed to collect information about household food and expenditure. It provides a valuable source of information about food purchases of the population, which can be translated into estimates of food consumption and nutrient intake (Wrieden et al., 2006). The survey however is not designed to measure intakes of specific individuals. The LCFS collects household food purchase and eating out data from every person over 7 years of age in each household over a 14-day period. However, LCFS data requires considerable secondary analysis to group the foods relevant to the Scottish Dietary Goals and calculate statistically meaningful figures. Due to the nature of household food purchase data, the LCFS cannot be used to give information on median intakes or classify consumption by age or gender (further advantages and disadvantages of the LCFS are discussed in Appendix 2). Therefore, the prevalence of individuals who are particularly high or low consumers of specific foods cannot be determined. The calculation of mean per capita consumption and nutrient intakes, with $95 \%$ confidence intervals, is not straightforward and requires a series of factors to be applied to the data. This process is essential if any meaningful comparisons are to be made between years and socio-economic factors such as deprivation (using the Scottish Index of Multiple Deprivation (SIMD)) (Scottish Government, 2012).

## Changes to Methodology over Time

Methods for the secondary analysis of the food purchase data of the LCFS and its predecessor (the EFS) have been further developed and improved since the original report (Wrieden et al., 2006). For example, in the original analysis all food purchase data was adjusted by subtracting $10 \%$ to take account of wastage following a similar procedure used by Defra in their analysis of the National Food Survey (NFS) and EFS and LCFS data. Following the publication of the Waste and Resource Action Programme (WRAP) survey (Waste and Resource Action Programme Survey (WRAP), 2008), Defra provided new figures which were based on more recent estimations of waste which varied according to food group. The data from 2001 onwards was subsequently revised to incorporate improvements to the methodology as follows:

1. Account for free food (e.g. from school meals, meals on wheels etc.). Defra adjusted the EFS data since the results of the secondary analysis published in 2006 (Wrieden et al., 2006) and have backdated these changes to 2001.
2. Adjust for waste using new factors following the publication of the 2008 WRAP report (Waste and Resource Action Programme Survey (WRAP), 2008).
3. Include factors to account for the LCFS sampling methodology.
4. Make use of a refined coding frame to allocate specific proportions of foods to appropriate food groupings.

## Coding Frames

The detailed coding frame reported by Barton et al. (2010) compiled for both household and eating out food purchases was re-ordered in line with the Scottish Dietary Goals and used for the analysis (Appendix 3). This was based on that reported by Wrieden et al. (2006) which provides further detail on its derivation and on the disaggregation of foods where appropriate. The coding frame is based on 522 food codes allocated by Defra to household or eating out food purchases. It lists groupings of foods (and codes) which form part of each dietary goal (or food group of interest) and gives details of conversion factors applied to the food weights. Conversion factors are necessary to apply the proportion of the food code applicable to the target food - for example, the vegetable contribution of vegetarian dishes is x0.4, a factor calculated from the NDNS adults 19-64 (Henderson et al., 2002). Where no factor was necessary, a factor of 1.0 was applied. Due to the type of data it is not possible to put a ceiling on the contribution that fruit juice and baked beans make to total fruit and vegetable intake and " 5 -a-day" as often happens in dietary survey reporting. It was decided following the Wrieden et al. (2006) report to only report total fruit and vegetable intake rather than with and without fruit juice and baked beans. This decision was based on the fact that average fruit juice intake from 2001-2003 was 42g/day and average baked bean consumption was $12 \mathrm{~g} /$ day, therefore well below the ceilings usually applied to fruit juice and baked beans of one 80 g portion per day.
The coding frame for energy density (Appendix 4) was compiled in a similar way (Wrieden and Barton, 2011); it indicates which foods/drinks were included within the food and milk method of calculating energy density and lists conversion factors. Foods which may not be consumed in their purchased state e.g. flour, stock cubes, jelly cubes were given a conversion factor of 1 as it was not possible to tell how these foods may be prepared and subsequently consumed.

## Categorisation of Foods

The Defra EFS coding frames for household and eating out food purchases were examined and foods forming part of each dietary goal (or additional foods and drinks indicative of diet quality) were selected and categorised accordingly.

## Conversion Factors

The conversion factors are applied to food purchases to estimate the actual amount of each food that is consumed. A conversion factor was calculated (for each food code, for household and eating out purchases); for the proportion of fruit, vegetable, meat etc. in a composite food; for the proportion of food in a food grouping (where it bridges more than one food grouping); raw to cooked weight (where appropriate); proportion of inedible waste; and estimate of edible waste. Data for these conversion factors were taken from the 1st, 2nd, 5th and 6th supplements of the $5^{\text {th }}$ edition of McCance and Widdowson's composition of foods (Chan et al., 1996, Chan et al., 1995, Holland et al., 1992a, Holland et al., 1992b). Where this data was not available from the above sources, information was sought from manufacturers' label data or market share data supplied by the Food Standards Agency. For details see Appendices 3 and 4.

## Edible Waste

Estimates of waste for the UK population were first published by WRAP in 2008. The annex of the report on the 2007 EFS (Department for Environment Food \& Rural Affairs (Defra), 2008) expands on the information available in the WRAP report and provides waste information at a more detailed level. Defra have mapped waste figures, based on those in the WRAP report, to each of the food codes used in the LCFS. This information was obtained from Defra and used to assign a waste factor to each food code. The waste figures were provided for single and multiple adult households and were linked to the appropriate type of household prior to analysis. The figures published by WRAP account for edible waste; inedible waste (i.e. bone) was taken into account when calculating the conversion factor for each food code. WRAP waste figures for Scotland were published in 2009 (WRAP Scotland, 2009), however these could not be used in the current analysis as data was not available as a percentage of individual foods/food groups and therefore no mapping to Defra food codes could be carried out on this regional data. Likewise, the UK 2009 update (WRAP, 2009) did not provide waste as a percentage of individual foods/food groups. For details see Appendix 5.

## Data Handling

LCFS data for each year, in its raw form, was obtained from the UK Data Archive, University of Essex (or from Defra and ONS ahead of it being made available from the UK Data Archive). The data comprised 3 files for each year - an Access (Microsoft Corporation) database containing raw data (at the household level) for food and drink purchases; and 2 SPSS (IBM Corporation) files - one containing information on each household (HH file) and the other containing information on each person within each household (PP file). Appendix 6 provides a flowchart which illustrates the data handling process for data from each year, which are then merged in SPSS to obtain one working data file. The Scottish sample of the LCFS for each year was extracted from the Access database and the HH and PP SPSS files. Each household was allocated a new ID due to overlap in Case IDs between years.
Data on sampling strata and clusters, household income and SIMD quintile were obtained from the UK ONS. Data on SIMD by postcode were initially obtained from Scottish Neighbourhood Statistics and sent to ONS to link to anonymised case ID's.

## Food Purchase Data

The Access database containing the Scottish food purchase data was linked to a table constructed from the coding frame, which listed each food grouping, each food within these groupings and the appropriate conversion factor to be applied to the calculations (where no factor was necessary 1.0 was applied). This table also contained data on waste for single and multiple adult households. Single and multiple adult households were selected in turn, the appropriate adjustment was then made for waste and the databases re-joined.
For foods: household and eating out consumption data minus waste (based on purchases) for each food code was multiplied by the appropriate conversion factor and summed by food grouping. This was then divided by the number of individuals in the household and divided by 14 to obtain the mean daily consumption per person.

For nutrients: household consumption data minus waste (based on purchases) for each food code was multiplied by the appropriate nutrient content per gram (provided by Defra) to provide the nutrient intake per food. Household, eating out and combined nutrient intakes for foods were then summed for each household. These were then divided by the number of individuals in the household and divided by 14 to obtain the mean daily intake per person for each nutrient.

Energy density for food and milk was calculated using the methodology developed by Wrieden et al. (2014) in three stages in MS Access and quintiles of energy density were calculated in SPSS by year (to negate any difference in energy density quintile over time).

1. Calculating weight of food/milk - the total weight of food/milk for each household was calculated by summing the weights of each food after making adjustments for waste and multiplying by the conversion factors described previously.
2. Calculating energy content of food/milk - the total energy from food/milk for each household was calculated by summing the energy content of each food after making adjustments for waste only, as the nutrient values in the database are based on the foods in their purchased form and not in the form, they are consumed.
3. Calculating energy density - the energy density values per 100 g for each household were calculated by dividing the total household energy content for food/milk (2) by the total household weight for food/milk (1) and multiplying by 100.

## Derivation of Household Variables Required for Analysis Purposes

Descriptive variables for each household were extracted from the two SPSS files described previously and merged with data on sampling strata and clusters, household income and SIMD, to form a SPSS file containing all household variables.

## Analysis of Data

The food consumption and nutrient intake data were exported to SPSS and merged with the household variables file. Due to the multi-staged stratified sampling procedure of the LCFS, data were analysed using Descriptive Statistics and General Linear Models within the Complex Samples module of SPSS and weighted according to the Scottish population. The data were weighted so that estimates obtained for mean food consumption and nutrient intake more accurately reflected that of the Scottish population. The weights were provided by Defra.
Linear associations between food consumption/ nutrient intake/ energy density and year or SIMD quintile were assessed by general linear modelling which was used to obtain estimates of the means with $95 \%$ confidence intervals $(95 \% \mathrm{Cl})$ and associated p -values. Overall associations between food consumption/ nutrient intake/ energy density, and year or SIMD quintile were assessed by adjusted Wald tests. The adjusted Wald test was used within regression analyses to test whether the value for all years or SIMD categories was equal or whether there was at least one difference between year or SIMD quintile. P-values $\leq 0.01$ are highlighted in bold to indicate significance at the $1 \%$ level.

## Appendix 2: Advantages and Disadvantages of the LCFS

The EFS/LCFS and their predecessor, the NFS, are annual household budget surveys designed to collect information about household food and expenditure. Further details about the design of the EFS/NFS are discussed in an earlier report (Wrieden et al., 2003). The EFS/LCFS provide a valuable source of information about the food purchases of the population, which can be translated into estimates of food consumption and nutrient intake (Wrieden et al., 2006). The survey however is not designed to measure intakes of specific individuals. The LCFS collects household food purchase data from every person over 7 years of age in each household for a 14-day period. The length of time the food diaries are kept (14 days) is a major strength of this study, as for most foods and nutrients the balance of intake is over more than 7-10 days. Methods that assess diet over shorter periods of time, e.g. three to four or less days, are less likely to give an accurate measure of intake. Due to the nature of the data collected in household budget surveys it is not possible to produce median intakes. Therefore, the prevalence of individuals who are particularly high or low consumers of a food, food group or nutrient cannot be determined.

## Advantages

- The LCFS includes around 550 households (approximately 1,300 people) per year in mainland Scotland.
- It collects information over a period of 14 days on food and drink purchases and includes foods eaten within the household and those eaten out.
- The LCFS records food acquisitions rather than consumption and is therefore possibly less susceptible to under-reporting and non-response bias than weighed intake dietary surveys (Chesher, 1997).
- The LCFS is one of the few publically available sources of information on food purchased out of the home. This can be compared with consumption in the home.
- It can be used to assess all the Scottish Dietary Goals (except salt and NMES in children), using the varieties and composition of food groups which were developed for the Barton et al. (2010) report.
- Data is collected continuously and published annually; it is possible to merge datasets over a number of years.
- Further information can be gained by linkage of data from the LCFS to the SIMD (for more information see (Scottish Executive, 2004, Scottish Government, 2012) respectively).

## Disadvantages

- The information collected is based on food purchased rather than actually eaten, so specific wastage factors are incorporated for different food groups, based on recent research by WRAP (2008). Although this is an improvement on the previously used $10 \%$ estimation of waste for all foods, the figures are based on research carried out in England and do not include flat dwelling households.
- Results obtained are an estimate of the consumption of a typical average household member so no information can be derived regarding the consumption by specific sub-groups e.g. children.

## Appendix 2: Advantages and Disadvantages of the LCFS / EFS

- Median and other distributional characteristics relating to consumption cannot be estimated.

Appendix 3: Monitoring Scottish Dietary Goals and Additional Foods and Drinks Indicative of Diet Quality Coding Frame

## Appendix 3: Monitoring Scottish Dietary Goals and Additional Foods and Drinks Indicative of Diet Quality Coding Frame

This updated and simplified coding frame is based on that reported by Wrieden et al., (2006), which provides information on the disaggregation of foods where appropriate. Appendix 1 provides further detail on the coding frame.

## 1. Dietary Goal: Average intake of a variety of fruit and vegetables to reach at least 5 portions per day ( $>400 \mathrm{~g}$ per day)

1. Fruit and Vegetables including fruit (and vegetable) juice and baked beans (addition of 2 and 4 )
2. Fruit including fruit (and vegetable) juice
3. Fruit (and vegetable juice)
4. Vegetables including baked beans

Household Fruit - including fruit (and vegetable) juice

| Defra Code | Food Description | Factor | Single <br> Adult HH <br> Waste | Multiple Adult HH Waste |
| :---: | :---: | :---: | :---: | :---: |
| 19603 | Vegetable juices e.g. tomato juice, carrot juice | 1 | 0.1 | 0.1 |
| 21001 | Fresh oranges | 1 | 0.3382 | 0.2325 |
| 21401 | Other fresh citrus fruits | 1 | 0.0536 | 0.041 |

No / low energy drinks
Alcohol

## Appendix 5: Defra Food Codes with Recommended Estimates of Edible Food Waste

The following figures for estimated waste are from the Waste and Resource Action Programme Survey (WRAP) (2008). The incorporation of these figures in the estimation of food and nutrient intakes from the EFS were discussed in the Annex of the 2007 Family Food report (Department for Environment Food \& Rural Affairs (Defra), 2008) and were mapped to the EFS food codes for this purpose by Defra (personal communication).

| Defra Code | Description | Single Adult Waste | Multiple Adult Waste |
| :---: | :---: | :---: | :---: |
| 402 | UHT whole milk | 0.1 | 0.1 |
| 403 | Sterilised whole milk | 0.1 | 0.1 |
| 404 | Pasteurised or homogenised whole milk | 0.1 | 0.1 |

| 300103 | Cereal bars and cereal based cakes | 71 | Total Confectionery and Sweet Biscuits | 1 |

Appendix 9: Slope Index of Inequality and Relative Index of Inequality

## Appendix 9: Slope Index of Inequality and Relative Index of Inequality

The Slope Index of Inequality (SII) was calculated as a measure of inequality of food consumption and nutrient intake. The SII is a measure of absolute inequality (ScotPHO, 2007) used to assess the absolute difference between the least and most deprived individuals. The SII was derived by ranking each household by SIMD (within the 3-year period SIMD was investigated within i.e. 2001-2003, 2004-2006, 2007-2009, 2010-2012 and 20132015). The rank scores obtained were divided by the sample size (for the appropriate 3-year period) to obtain a value between 0 and 1, weighted to the relative distribution across SIMD quintiles. Linear regression analysis (weighted least squares) of the mean intake within each SIMD quintile was used to calculate the SIls for each food / nutrient. The regression (or slope) coefficient from the regression analysis is the SII. For interpretation purposes the SII is the mean difference in intake between the hypothetically most deprived relative to the hypothetically least deprived person in the population (Shaw et al., 2007).

In order to compare a measure of inequality across populations or years, the relative index of inequality (RII) was calculated, which is the SII divided by the overall population mean food consumption or nutrient intake. This helps when making comparisons of the magnitude of the association between the same socio-economic position measures over time. For both SII and RII, the underlying assumption is that there is a linear gradient across the deprivation variable.

The SII figures provide the absolute difference between the hypothetically most deprived and the hypothetically least deprived person for each of the foods / nutrients. A positive figure indicates that consumption / intake is higher in the least deprived and a negative figure indicates that consumption / intake is greatest in the most deprived.

SII and RII figures with 95\% CI were calculated for 2001-2003, 2004-2006, 2007-2009, 2010-2012 and 20132015 to allow a comparison to be made over time of absolute and relative differences. Whilst they were calculated for all foods and nutrients, it is acknowledged that a linear difference was not found for all foods and nutrients for each of the 3-year time periods. The results show that absolute and relative inequalities in food/nutrient intakes have not changed appreciably between 2001 and 2015. The magnitude of the inequalities is substantial for some foods, e.g. fruit and vegetables where the mean intake in the most deprived was the equivalent of around 2 portions less than the least deprived.

[^11]Appendix 10: Mean Food Consumption and Nutrient Intake Results by Year
Figure D: Mean [95\% CI] energy density (food and milk) by year 2001-2015 compared to the 2013 Scottish Dietary Goal (125 kcal/100g)

$P($ linear association $)=0.007 ; P($ overall association $)=0.146$

Figure E: Mean [95\% CI] fat intake by year 2001-2015 compared to the 2013 Scottish Dietary Goal (<35\% food energy)

$P($ linear association $)=0.053 ; P($ overall association $)=0.791$

Appendix 10: Mean Food Consumption and Nutrient Intake Results by Year
Figure F: Mean [95\% CI] saturated fat intake by year 2001-2015 compared to the 2013 Scottish Dietary Goal ( $\leq 11 \%$ food energy)

$P($ linear association $)=0.014 ; P($ overall association $)=0.035$

Figure G: Mean [95\% CI] NMES intake by year 2001-2015 compared to the 2013 Scottish Dietary Goal ( $\leq 11 \%$ food energy)

[^12]Appendix 10: Mean Food Consumption and Nutrient Intake Results by Year
Figure H: Mean [95\% CI] NSP intake by year 2001-2015 compared to the 2013 Scottish Dietary Goal (18g/day)

$P($ linear association $)=0.046 ; P($ overall association $)=0.325$
